

Setting up Tripwire with SSMTP

Contents

1 Overview	1
2 Steps	1
2.1 Configuring Tripwire	1
2.1.1 Devuan/Debian	1
2.2 Configuring SSMTP	4

This document is best read printed out on paper.

1 Overview

Tripwire is intrusion detection software for GNU Linux & BSD. Let's document how to set it up on a server with SSMTP configured for email notifications. Tripwire isn't too hard to setup, but I had to jump through a hoop for email notifications. Here I cover install, and how to get SSMTP working.

2 Steps

2.1 Configuring Tripwire

First install Tripwire. This will depend on your package manager. The two examples I have will be either Gentoo, or Debian/Devuan.

```
apt-get install tripwire mailutils ssmtp  
OR  
emerge -av tripwire mailutils ssmtp
```

2.1.1 Devuan/Debian

Devuan will prompt you for a few things in an ncurses gui. Answer all of the defaults (yes for a site key, yes for a user key, etc...). Record your password.

¹ I use the same password for both.

¹For a full walkthrough of this process see this URL:<https://www.howtoforge.com/tutorial/how-to-monitor-and-detect-modified-files-using-tripwire-on-ubuntu-1604/> This process includes most, but not all of what you need

After install:The goal when setting this up is to init, as little as possible. Each init is about 2-3 minutes, so time can be avoided, if you know what configs you need. Let's first edit the configs as much as possible.

when whitelisting, this is what needs to be commented out in devuan jessie/ascii for

```
Filename: /etc/rc.boot
Filename: /root/mail
Filename: /root/Mail
Filename: /root/.xsession-errors
Filename: /root/.xauth
Filename: /root/.tcshrc
Filename: /root/.sawfish
Filename: /root/.pinerc
Filename: /root/.mc
Filename: /root/.gnome_private
Filename: /root/.gnome-desktop
Filename: /root/.gnome
Filename: /root/.esd_auth
Filename: /root/.elm
Filename: /root/.cshrc
Filename: /root/.bash_profile
Filename: /root/.bash_logout
Filename: /root/.amandahosts
Filename: /root/.addressbook.lu
Filename: /root/.addressbook
Filename: /root/.Xresources
Filename: /root/.Xauthority
Filename: /root/.ICEauthority
Filename: /proc/6136/fd/3
Filename: /proc/6136/fdinfo/3
Filename: /proc/6136/task/6136/fd/3
Filename: /proc/6136/task/6136/fdinfo/3
```

For proc, you simply comment out the whole directory. (you'll see an entry in the file for /proc, put a # before that). After twpol, we are not done. We also need to edit the email settings.

In /etc/tripwire/twcfg.txt we will change the following:

to know.

```
MAILMETHOD      =SENDMAIL
MAILPROGRAM =/root/script.sh
```

script.sh is just a script: (make sure it is executable with `chmod +x`²)

```
#!/bin/bash
/usr/sbin/sendmail -s youremail@domain.com
```

Finally, the last change we might make, will be for any special directories we want to watch. I put websites in the root at `/sites/` so I will append the following to `/etc/tripwire/twpol.txt`

```
# Ruleset for Website
(
  rulename = "Website Ruleset",
  severity= $(SIG_HI)
)
{
    /sites/          -> $(SEC_CRIT);
}
}
```

Now we will init, type

```
sudo tripwire --init
sudo twadmin -m P /etc/tripwire/twpol.txt
sudo tripwire --init
```

to reconfigure `twcfg.txt` run

```
/usr/sbin/twadmin --create-cfgfile -S site.key /etc/tripwire/twcfg.txt
if you get:
```

```
root@site:~# /usr/sbin/twadmin --create-cfgfile -S site.key /etc/tripwire/twcfg.txt
# Error: File could not be opened.
# Filename: /root/site.key
# No such file or directory
# Exiting...
```

You must `cd` to `/etc/tripwire` directory.

²This script appears to be required in this setup.

2.2 Configuring SSMTP

SSMTP is a program you configure once, and can reuse the configuration everywhere³. For starters, I'd recommend you install SSMTP according to this guide here:

https://wiki.zoneminder.com/How_to_get_ssmtp_working_with_Zoneminder

This is a thorough guide that explains debugging. Some steps are superfluous (given that the instructions pertain to different software) but the general directions are sound. And afterwards sending an email is as easy as

```
echo "Hello, World" |mail -s "My email check" user@email.com
```

This guide assumes you have configured SSMTP according to this guide correctly, tested it, and are able to mail from the command line. Once you've setup SSMTP once, you can reproduce this setup on other computers, simply by copying over the revalias and ssmtp.conf of a valid configuration.

So let's do that. Copy over revalias, and ssmtp.conf. test the configuration from the command line using the above echo and mail. Once that works, test out tripwire.

```
tripwire -test -email user@email.com
```

Done.

³This is a strength of FOSS and let it remain that way.
