Setting up Tripwire with SSMTP

Contents

This document is best read printed out on paper.

1 Overview

Tripwire is intrusion detection software for GNU Linux & BSD. Let's document how to set it up on a server with SSMTP configured for email notifications. Tripwire isn't too hard to setup, but I had to jump through a hoop for email notifications. Here I cover install, and how to get SSMTP working.

2 Steps

2.1 Configuring Tripwire

First install Tripwire. This will depend on your package manager. The two examples I have will be either Gentoo, or Debian/Devuan.

```
apt-get install tripwire mailutils ssmtp
OR
emerge -av tripwire mailutils ssmtp
```

2.1.1 Devuan/Debian

Devuan will prompt you for a few things in an ncurses gui. Answer all of the defaults (yes for a site key, yes for a user key, etc...). Record your password. [1] I use the same password for both.

---

[1]For a full walkthrough of this process see this URL:https://www.howtoforge.com/tutorial/how-to-monitor-and-detect-modified-files-using-tripwire-on-ubuntu-1604/ This process includes most, but not all of what you need

After install: The goal when setting this up is to init, as little as possible. Each init is about 2-3 minutes, so time can be avoided, if you know what configs you need. Let's first edit the configs as much as possible.

```
when whitelisting, this is what needs to be commented out in devuan jessie/ascii for
```

```
Filename: /etc/rc.boot
  Filename: /root/mail
  Filename: /root/Mail
  Filename: /root/.xsession-errors
  Filename: /root/.xauth
  Filename: /root/.tcshrc
  Filename: /root/.sawfish
  Filename: /root/.pinerc
  Filename: /root/.mc
  Filename: /root/.gnome_private
  Filename: /root/.gnome-desktop
  Filename: /root/.gnome
  Filename: /root/.esd_auth
  Filename: /root/.elm
  Filename: /root/.cshrc
  Filename: /root/.bash_profile
  Filename: /root/.bash_logout
  Filename: /root/.amandahosts
  Filename: /root/.addressbook.lu
  Filename: /root/.addressbook
  Filename: /root/.Xresources
  Filename: /root/.Xauthority
  Filename: /root/.ICEauthority
  Filename: /proc/6136/fd/3
  Filename: /proc/6136/fdinfo/3
  Filename: /proc/6136/task/6136/fd/3
  Filename: /proc/6136/task/6136/fdinfo/3
```

For proc, you simply comment out the whole directory. (you'll see an entry in the file for /proc, put a # before that). After twpol, we are not done. We also need to edit the email settings.

In /etc/tripwire/twcfg.txt we will change the following:

---

to know.

```
MAILMETHOD     =SENDMAIL
MAILPROGRAM =/root/script.sh
```

script.sh is just a script: (make sure it is executable with chmod +x[2])

```
#!/bin/bash
/usr/sbin/sendmail -s youremail@domain.com
```

Finally, the last change we might make, will be for any special directories we want to watch. I put websites in the root at /sites/ so I will append the following to /etc/tripwire/twpol.txt

```
# Ruleset for Website
(
  rulename = "Website Ruleset",
  severity= $(SIG_HI)
)
{
        /sites/          -> $(SEC_CRIT);
}
```

Now we will init, type

```
sudo tripwire --init
sudo twadmin -m P /etc/tripwire/twpol.txt
sudo tripwire --init
```

to reconfigure twcfg.txt run
/usr/sbin/twadmin –create-cfgfile -S site.key /etc/tripwire/twcfg.txt
if you get:

```
root@site:~# /usr/sbin/twadmin --create-cfgfile -S site.key /etc/tripwire/twcfg.txt
# Error: File could not be opened.
# Filename: /root/site.key
# No such file or directory
# Exiting...
```

You must cd to /etc/tripwire directory.

---

[2]This script appears to be required in this setup.

2.2 Configuring SSMTP

SSMTP is a program you configure once, and can reuse the configuration everywhere[3]. For starters, I'd recommend you install SSMTP according to this guide here:

`https://wiki.zoneminder.com/How_to_get_ssmtp_working_with_Zoneminder`

This is a thorough guide that explains debugging. Some steps are superfluous (given that the instructions pertain to different software) but the general directions are sound. And afterwards sending an email is as easy as

echo "Hello, World" |mail -s "My email check" user@email.com

This guide assumes you have configured SSMTP according to this guide correctly, tested it, and are able to mail from the command line. Once you've setup SSMTP once, you can reproduce this setup on other computers, simply by copying over the revaliases and ssmtp.conf of a valid configuration.

So let's do that. Copy over revaliases, and ssmtp.conf. test the configuration from the command line using the above echo and mail. Once that works, test out tripwire.

tripwire --test --email user@email.com

Done.

---

[3]This is a strength of FOSS and let it remain that way.
